XPS/UPS – Ryan Davies
EFM – Andy Gerger
XPS/ESCA

X-ray photoelectron spectroscopy (XPS) also called Electron Spectroscopy for Chemical Analysis (ESCA) is a chemical surface analysis method. XPS measures the chemical composition of the outermost 100 Å of a sample. Measurements can be made at greater depths by ion sputter etching to remove surface layers. All elements (except for H and He) can be detected at concentrations above 1.0 atom %. In addition, chemical bonding information can be determined from detailed analysis.

A Ga 3d peak with 2 curves fitted. Can determine relative concentration of Ga-O and Ga-N.
XPS/UPS

XPS/ESCA Perkin-Elmer PHI 5100 ESCA System - MAIC

1. X-ray source – Mg or Al anode
2. Sample
3. Lens and aperture
4. Hemisphere energy analyzer
5. Position Sensitive Detector
6. Data Collection - Computer
Used XPS to determine the surface composition/contamination and nature of the chemical bonding.

Oxygen surface conc. increases with ozone exposure time, however, oxygen depth does not. Surface converted to an oxynitride. (sample temperature~50°C)

Surface carbon concentration reduced 50% by conversion to CO and CO₂.
Past XPS use on HEMT passivation optimization

Oxynitride on AlGaN(23%) capped HEMT

Native Oxide
(0.7eV surface charge)

A 21st Century Approach to Reliability
Past XPS use on HEMT passivation optimization

Ga 3d from GaN capped HEMT

As-Received GaN Surface

Notice the decrease in the GaO_x portion (corresponding with sputter time) and the shift in the Ga 3d signal as surface charge is reduced.
As x-rays enter the material, photo-electrons are generated from different depths. Thick (2nm) ozone GaON is not conductive; electrons leaving the surface are not replenished from the bulk. Large surface charge (4.8eV) is indicated from XPS spectra shift.

GaN capped HEMTs show better passivation than AlGaN capped HEMTs.

Increase in Al% = increase in surface reactivity = less passivation.
Large scale features to aid in optimization

Effects on Isolation Current
mesa to mesa leakage measurements

Must have isolation for realization of HEMT circuits.
Large scale features to aid in optimization

Passivation Reliability

Hall effect samples (5mm x 5mm) are processed to determine the passivation effect of the dielectric films. Samples are aged at elevated temperatures to determine effectiveness.

Hall samples are large enough for further analysis (AFM, AES, XPS) for post aging studies.

Hall sample w/ 10nm MgO passivation, a 15% increases in sheet carrier density post passivation
Small spot XPS/UPS

Custom XPS/UPS on Nitride MBE system allows for sample transfer without exposure to atmosphere, 3” wafer capable. Intermediate chamber available for additional processing or testing.

System based on a PHI 5400 XPS - Area resolution is <500µm, 2500mm² viewing area.

Aging of samples by both thermal stress (800°C sample heater) and bias stress (electrical feedthru to sample). Surface chemical desorption experiments and real-time diffusion data possible with sample heater.

Ultraviolet He arc discharge source installed for UPS
What UPS adds to the package

Mainly used for studies of the valence electron density of states. The VUV (10-200nm) discharge covers a useful range from 10 to 50 eV photon energy. The line width of excitation is generally a few meV, excellent for resolving molecular vibrational structures.

UV excited photoelectron spectra could be used for a comparison with band structure calculations and (in comparison with XPS) providing some additional fingerprint information in surface chemical analysis. (ex. Determine Al$_2$O$_3$, AlPO$_4$, Al$_4$(P$_4$O$_{12}$)$_3$ on a sample)

Provides a high resolution valance band spectra compared to XPS for determining valance band on surfaces.
Reliability of dielectrics

Reliability (aging) of the dielectric can be determined through both thermal stress and bias stress to determine method of failure. (large area features)

The two regions for dielectric coverage have significantly different surface chemistries and structure.

Identify key interface species/reactions that lead to stable passivation, isolation or field plates dielectric.
Metal contact failure mechanism

Using AES (area = micron to submicron) one can easily determine certain metal contact failure mechanisms.

Example: Ni/Au gate contact

The Ni diffuses to the surface, leaving Au in contact with the AlGaN.

Fairly straight forward.
Metal contact failure mechanism

Failure of Ohmic contacts not as easily understood using AES.

Using AES one cannot determine the bonding state of the element, only the amount and depth position.

Example: A low resistivity ohmic contact is a blending of the different metals. Cannot determine if TiN interface formed.

Must use XPS.
Use of XPS can identify different sources of carbon contamination that are left behind from device processing.

Characterization enhanced with UPS

AES can only determine that C and O are present, but not the species or source.
XPS/UPS

Projected Milestones

Year 1- Characterize operational and failed devices in the mesa isolation region. Determine changes in surface chemistry and work function. Correlate chemical/electrical changes.

Year 2- Design test structures to be placed in the die cut lines. Apply test structures to the cut lines and investigate variations in surface chemistry from post field stressing.

Year 3- Design in-situ bias stressing fixture for XPS-UPS. Characterize cut line test structures under bias stress using XPS-UPS. Identify degradation mechanism. Investigate reactions of semiconductor/passivation interface.

Year 4- Real-time observation of near-surface changes during bias stressing.

Year 5- Small spot size XPS capability for direct analysis on die
Electrostatic force microscopy - EFM

Scan area in AFM Tapping mode, then apply a bias to the tip and scan in EFM mode.

Image of high aspect ratio EFM tip available from Veeco.

Veeco Dimension 3100 with Nanoscope V controller is currently installed in the MAIC facility
Electrostatic force microscopy - EFM

Applied to pre and post aged devices to scan for variations of the electric field on the device surface.

Examine defects propagating to the surface during testing, electromigration of gate metal in the gate-drain region, and increases in the surface potential from UV illumination emptying traps.

Identify area for TEM/LEAP.
Projected Milestones

**Year 1** – Map the device surface of operational devices varying substrate bias and tip bias. Establish scan parameters for various compound semiconductor surfaces.

**Year 2** – Map the device surface of failed devices and establish trends of failure in this region. Design probe cards for device biasing during scanning.

**Year 3** – Correlate the failure mode to evolution of defects observed by TEM/LEAP. Incorporate defect generation and field profile into simulators.

**Year 4** – Real-time imaging of devices during stressing

**Year 5** – Establish limits of predictive forecast of reliability using short bias-aging cycles.
xtra
High resolution XPS/UPS

State of the art tools have <9μm spot size and can build chemical maps of the surface – Physical Electronics & Omicron

High intensity monochromatic x-ray sources scan the surface.

Sphera – 60μm
NanoESCA – 650nm
Imaging Mode XPS/UPS

Imaging at high kinetic electron energies. Ag evaporated on Cu, 35 µm field of view, 20 min acquisition time on Ag 3d5/2.
